ABSTRACT:

The gene for occludin, an integral transmembrane protein specifically associated with tight junctions that functions in forming intercellular seal, is cloned, characterized, and sequenced, and the polypeptide sequence determined. Drug delivery is enhanced by administering an effective amount of occludin inhibitors. These include peptides or antibodies that interact with occludin or occludin receptors. Also included are occludin antagonists, occludin receptor components, and mixtures thereof. In some embodiments, analogues of occludin surface loops that inhibit adhesion and/or barrier properties are employed. Administration can be local or systemic; local administration in a pharmaceutically acceptable carrier is preferred in some embodiments.

PRIMARY-EXAMINER: Le; Long V. ASSISTANT-EXAMINER: Do; Pensee T.

ATTY-AGENT-FIRM: Rehberg; Edward F. Kerber; Lori L.

ABSTRACT:

The invention relates to novel fluorescence-based assays for protein kinases and phosphatases which can be used in high throughput screening. The methods of the invention utilize a competitive immunoassay to determine the amount of substrate that is phosphorylated or dephosphorylated during the course of a kinase or phosphatase reaction to yield a product, as well as the phosphorylating or dephosphorylating activity of a kinase or phosphatase.

ABSTRACT:

Two Hepatitis C Virus envelope proteins (El and E2) are expressed without sialylation. Recombinant expression of these proteins in lower eukaryotes, or in mammalian cells in which terminal glycosylation is blocked, results in recombinant proteins which are more similar to native HCV glycoproteins. When isolated by GNA lectin affinity, the El and E2 proteins aggregate into virus-like particles.

ABSTRACT:

A cloned DNA encoding phosphoenolpyruvate carboxykinase of a C.sub.4 plant is disclosed. The DNA according to the present invention encodes the amino acid sequence shown in SEQ ID NOS: 1-6 in Sequence Listing or the same amino acid sequence as shown in SEQ ID NOS: 1-6 except that one or more amino acid is added, deleted, inserted or substituted, with the proviso that the polypeptide having this amino acid sequence has phosphoenolpyruvate carboxykinase activity.

ABSTRACT:

A method of diagnosing renal diseases by detecting fragments of albumin in human urine. The detection of the fragments is carried out by, for example, immunological methods or liquid chromatography techniques.

ABSTRACTED-PUB-NO: WO 200035483A

BASIC-ABSTRACT:

NOVELTY - A method (M1) for inhibiting lectin complement pathway (LCP)-associated complement activation, comprising contacting a mammalian cell

having surface exposed mannose binding lectin (MBL) ligand with an MBL inhibitor to inhibit LCP-associated complement activation, is new.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (1) a composition comprising an MBL inhibitor, where the MBL inhibitor is an isolated binding peptide that selectively binds to a human MBL epitope and inhibits LCP associated complement activation;
- (2) hybridoma cell lines deposited under ATCC HB-12621, HB-12620, and HB-12619; and
- (3) a method (M2) for screening a cell for susceptibility to treatment with an MBL inhibitor comprising detecting the presence of a MBL on a surface of a mammalian cell, where the presence of the MBL indicates susceptibility to LCP associated complement activation and treatment with an MBL inhibitor.

ACTIVITY - Cardiant; antiarthritis; vasotropic; cerebroprotective; dermatological, immunosuppressive, antiinflammatory; respiratory.

 $\begin{tabular}{ll} {\tt MECHANISM} & {\tt OF} & {\tt ACTION} & - & {\tt MBL} & {\tt inhibitors} & {\tt inhibit} & {\tt LCP-associated} & {\tt complement} \\ {\tt activation}. \end{tabular}$

In order to demonstrate specifically the role of MBL in complement activation following oxidative stress of human endothelial cells, MBL and C3 deposition on hypoxic human endothelial cells following reoxygenation in human sera was assessed. To demonstrate the complement inhibitory action of these anti-human MBL monoclonal antibodies (mAbs), hypoxic HUVECs (human umbilical vein endothelial cells) were reoxygenated in human sera treated with PBS (phosphate buffered saline) (vehicle), 3F8, hMBLI.2, 2A9, or IC10 (50 micro q/ml final concentration). Cell membrane bound proteins were resolved by SDS-PAGE (sodium dodecyl sulfate-polyacrylamide gel electrophoresis) under reduced conditions, transferred to membranes, and analyzed for human C3dg (i.e., part of the alpha -chain of iC3b). The alpha and beta -chain of iC3b were the only C3 stainable bands present on the cellular membranes. A representative C3dg band for vehicle, 3F8-, hMBLI.2-, 2A9- and IC10-treated cells was observed. A significant decrease in C3dg band intensity on cells reoxygenated in human sera treated with either 3F8, 2A9 or hMBL1.2 was observed. However, the non-functional clone, IC10, did not decrease iC3b deposition (i.e., C3dg band intensity) on the endothelial membranes. These data supported the role of MBL-dependent complement activation following reoxygenation of hypoxic HUVECs. Further, the data confirmed that clone IC10 is an isotype control mAb that does not functionally inhibit MBL. Dual labeling for MBL and C3 deposition on normoxic and hypoxic HUVECs was performed to demonstrate co-localization of these complement components and MBL-dependent complement pathway activation. Normoxic and hypoxic HUVECs were reoxygenated in 30% HS (not defined) treated with and without mAb 3F8 (5 micro q/ml) or IC10 (50 micro q/ml). MBL (blue), C3 (green) and nuclei (red) were then stained on the same slide and analyzed by immunofluorescent confocal microscopy. Small amounts of C3 and MBL staining were observed under normoxic conditions. C3 and MBL staining on hypoxic/reoxygenated HUVECs was significantly greater than normoxic HUVECS. Clone IC10 failed to inhibit C3 or MBL deposition following oxidative stress. C3 and MBL staining was significantly decreased on hypoxic/reoxygenated HUVECs treated with mAb 3F8 (5 micro g/ml) to levels below those observed under normoxic conditions (similar results were observed with mAbs hMBL1.2 or 2A9). The data demonstrated that functional inhibition of MBL with a mAb attenuates C3 deposition following oxidative stress of human endothelial cells.

USE - Inhibition of complement associated activation is useful for the treatment of disorders such as arthritis, myocardial infarction, ischemia, reperfusion, transplantation, CPB (not defined), stroke, acute respiratory diseases (ARDs), systemic lupus erythematosus (SLE), lupus, and dialysis.

Binding of mannose-binding lectin (MBL), a C-type lectin, and its associated serine proteases, MASP-1 and MASP-2, to cell surface
                 AB
                                   Binding of mannose-binding lectin (MBL), a C-type lectin, and its associated serine proteases, MASP-1 and MASP-2, to cell surface carbohydrates activates the lectin complement pathway. As MBL plays an important role in innate immunity, it has been cloned and characterized in several species. While the pig may be used as a source of organs/tissues for xenotransplantation, little is known about its MBL, thus, we report the isolation of three monomeric forms of MBL from porcine serum. Sodium dodecyl sulphate-polyacined gel electrophoresis and Coomassie staining of reduced porcine MBL revealed the presence of three monomeric forms with approximate molecular masses of 30 000, 32 000 and 34 000. Protein sequencing identified these monomeric forms as one single protein, suggesting post-translational modification. WBL polyclonal antibody with porcine MBL. A full-length porcine liver MBL cDNA was isolated and the predicted amino acid sequence exhibited 64.9% identity with human MBL and 50.2% and 56.7% identity with rat A and C MBL, respectively. Furthermore, Northern blot analysis demonstrated the presence of a single (approximately 1.4-1.6 kilobase pair) transcript in porcine liver. Addition of purified porcine MBL to MBL-deficient human sera augmented N-acetylglucosamine inhibitable C3 deposition to mannan-coated plates in a dose-dependent manner. Taken together, these data demonstrate that porcine and human MBL are highly conserved, sharing structural and functional characteristics.
                                   characteristics.

The complement system plays an important role in mediating tissue injury after oxidative stress. The role of mannose-binding lectin (MBL) and the lectin complement pathway (LCP) in mediating complement activation after endothelial oxidative stress was investigated. iC3b deposition on hypoxic (24 hours; 1% O(2))/reoxygenated (3 hours; 21% O(2)) human endothelial cells was attenuated by N-acetyl-D-qlucosamine or D-mannose, but not L-mannose, in a dose-dependent manner. Endothelial iC3b deposition after oxidative stress was also attenuated in MBL-deficient serum. Novel, functionally inhibitory, anti-human MBL monoclonal antibodies attenuated MBL-dependent C3 deposition on mannan-coated plates in a dose-dependent manner. Treatment of human serum with anti-MBL monoclonal antibodies inhibited MBL and C3 deposition after endothelial oxidative stress. Consistent with our in vitro findings, C3 and MBL immunostaining throughout the ischemic area at risk increased during rat myocardial reperfusion in vivo. These data suggest that the LCP mediates complement activation after tissue oxidative stress. Inhibition of MBL may represent a novel therapeutic strategy for ischemia/reperfusion injury and other complement-mediated disease states.

PRIORITY APPLN. INFO:

AB The invention relates to methods and products for regulating lectin complement pathway assocd. complement activation. The methods include both in vitro and in vivo methods for inhibiting lectin complement pathway assocd. complement activation. The methods are accomplished by contacting a mammalian cell having surface exposed MBL ligand with an effective amt. of a mannan binding lectin (MBL) receptor antagonist to inhibit lectin complement pathway assocd. complement activation. The mannan binding lectin receptor antagonist. The products of the invention include compns. of a mannan binding lectin receptor antagonist. The mannan binding lectin receptor antagonist is an isolated mannan binding lectin that selectively binds to

The invention relates to methods and products for regulating lectin complement pathway assocd. complement activation. The methods include both in vitro and in vivo methods for inhibiting lectin complement pathway assocd. complement activation. The methods are accomplished by contacting a mammalian cell having surface exposed MBL ligand with an effective amt. of a mannan binding lectin inhibitor to inhibit lectin complement pathway assocd. complement activation. The mannan binding lectin inhibitor may be administered to a subject to prevent cellular injury mediated by lectin complement pathway assocd. complement activation. The products of the invention include compns. of a mannan binding lectin inhibitor. The mannan binding lectin inhibitor is an isolated mannan binding lectin binding peptide that selectively binds to a human mannan binding lectin epitope and that inhibits lectin complement pathway assocd. complement activation. The products also include hybridoma cell lines and pharmaceutical compns.

Complement is a major participant in post-ischemic reperfusion injury. The classical and alternative complement pathways have been extensively studied; however, the role of the lectin complement pathway (LCP) in inflammation has not been investigated since inhibitors of MBL have not been described. In order to delineate the participation of the LCP, we generated antibodies to
                  since inhibitors of MBL have not been described. In order to delineate the participation of the LCP, we generated antibodies to rat mannose binding lectin (MBL).

In this study, antibodies (Ab) were produced and characterized for potential use in further dissecting the role of the LCP in rat models of human disease. Polyclonal and monoclonal antibodies were produced in rabbits and mice using purified MBL isolated from rat sera by affinity chromatography and standard immunization techniques. All antibodies were screened using 2 different ELISA systems (binding to mannan or BSA coupled to N-acetyl-D-glucosamine; BSA-GlcNAC) to detect complement activation and deposition of C3. Monoclonal Ab P7E4 inhibited C3 deposition onto BSA-GlcNAC coated plates in a concentration-dependent manner with maximal inhibition (apprx80%) occurring at 10 mug/mL. Similarly, Fab fragments of the polyclonal antibody inhibited complement deposition in a concentration dependent manner. Western blot analysis was performed to determine the isoform(s) of rat MBL that the antibodies recognized. While the polyclonal Ab recognized multiple oligomers of A and C isoforms under non-reducing conditions, mAb P7E4 only recognized the A isoform. Similar results were obtained under reducing conditions in that the polyclonal Ab recognized both forms while only the A isoform was recognized by P7E4. These data confirm that the antibodies recognize rat mannose binding lectin, inhibit the function of MBL and may serve as useful reagents in studying the lectin complement pathway in rat models of human disease.

Reperfusion of ischemic myocardium initiates an inflammatory-like process leading to additional tissue injury. Following myocardial ischemia and reperfusion (MI/R), complement is activated with a subsequent increase in pro-inflammatory cytokines and adhesion molecule gene expression.
Increasing evidence suggests that the lectin complement cascade following MI/R. In this study, we assessed the result of inhibiting complement activation via the LCP on the expression of inflammatory genes (cytokines and adhesion molecules) following MI/R. Male Sprague-Dawley rats were subjected to 30 minutes of ischemia followed by 4 hours of reperfusion. Prior to occlusion, rats were treated with 1 mg/kg PTE4 (a mab against rat mannose binding lectin-MBL A) or GS-1 (an isotype control antibody). Following 4 hours of reperfusion, the hearts were removed, washed in saline and the area at risk was frozen in liquid nitrogen. Total RNA was isolated using the acid-quanidinium thiocyanate extraction procedure and subjected to DNAse treatment. Semi-quantitative controls. Inhibition of MSL A attenuated the increased expression of ICAM-1*, iNOS*, TNF-alpha*, GM-CSF* and IL-1 alpha* compared to sham operated animals and those treated with GS-1 or PTE4 as described above.

Ischemia-reperfusion resulted in the increased expression of ICAM-1*, iNOS*, TNF-alpha*, GM-CSF* and IL-alpha* compared to sham operated controls. Inhibition of MBL A attenuated the increased expression for ICAM-1*, CM-CSF*, IL-1 alpha* and iNOS. These data suggest that inhibition of MBL and the lactin complement pathway results in the attenuation of inflammatory gene expressio

US 1998-112390 P 19981215

The invention relates to methods and products for regulating lectin complement pathway assocd. complement activation. The methods include both in vitro and in vivo methods for inhibiting lectin complement pathway assocd. complement activation. The methods are accomplished by contacting a mammalian cell having surface exposed MBL ligand with an effective amt. of a mannan binding lectin inhibitor to inhibit lectin complement pathway assocd. complement activation. The mannan binding lectin inhibitor may be administered to a subject to prevent cellular injury mediated by lectin complement pathway assocd. complement activation. The products of the invention include compns. of a mannan binding lectin inhibitor. The mannan binding lectin inhibitor is an isolated mannan binding lectin binding peptide that selectively binds to a human mannan binding lectin
                   binding peptide that selectively binds to a human mannan binding lectin epitope and that inhibits lectin complement pathway assocd. complement activation. The products also include hybridoma cell lines and
                    pharmaceutical compns.

bind to MBL and functionally inhibit the car on endothelial cells following oxidative stress. Using a BIAcore 3000 optical biosensor, competition experiments were performed to demonstrate that the peptide SFGSGFGGGY inhibits binding of purified recombinant human MBL to GlcNAc in a concentration-dependent manner. Solution affinity data generated by BIAcore indicate this peptide binds to MBL with an affinity (K(D)) of 5 x 10(-5) mol/L. Pretreatment of human serum (30%) with the GlcNAc-mimicking peptide (10-50 microg/ml) significantly attenuated MBL and C3 deposition on human endothelial cells subjected to oxidative stress in a dose-dependent manner, as demonstrated by cell surface. . VCAM-1 expression following oxidative stress. These data indicate that a short peptide sequence that mimics GlcNAc can specifically bind to MBL and functionally inhibit the proinflammatory action of the LCP on oxidatively stressed endothelial cells. Reperfusion of ischemic myocardium initiates an inflammatory-like process leading to additional tissue injury. Following myocardial ischemia and reperfusion (MI/R), complement is activated with a subsequent increase in pro-inflammatory cytokines and adhesion molecule gene expression. Increasing evidence suggests that the lectin complement pathway (LCP) is involved in initiating the complement cascade following MI/R. In this study, we assessed the result of inhibiting complement activation via the LCP on the expression of inflammatory genes (cytokines and adhesion molecules) following MI/R. Male Sprague-Dawley rats were subjected to 30 minutes of ischemia followed by 4 hours of reperfusion. Prior to occlusion, rats were treated with 1 mg/kg PT& (a mAb against rat mannose binding lectin-MBL A) or GS-1 (an isotype control antibody). Following 4 hours of reperfusion, the hearts were removed, washed in saline and the area at risk was frozen in liquid nitrogen. Total RNA was isolated using the acid-guanidinium thiocyanate extraction procedure and subjected to DNAse treatment. Semi-quantitative RT-PCR was performed to assess mRNA levels of ICAM-1, TNF-alpha, iNOS, eNOS, SOD (Cu/Zn and Mn) GM-CSF and IL-1 alpha, in sham operated animals and those treated with GS-1 or PT&4 as described above. Ischemia-reperfusion resulted in the increased expression of ICAM-1*, iNOS*, TNF-alpha*, GM-CSF*, IL-1 alpha* and iNOS. These data suggest that inhibition of MBL A and the lectin complement pathway results in the attenuation of inflammatory gene expression and that this gene regulation may be partially responsible for the protection from MI/R injury, * p < 0.05.

porcine serum. Sodium dodecyl sulphate-por-crylamide gel electrophoresis and Coomassie staining of reduced porcine MBL revealed the presence of three monomeric forms with approximate molecular masses of 30 000, 32 000 and 34 000. Protein sequencing identified these monomeric forms as one single protein suggesting proteins. presence of three monomeric forms with approximate molecular masses or 30 000, 32 000 and 34 000. Protein sequencing identified these monomeric forms as one single protein, suggesting post-translational modification. Western blot analysis demonstrated the cross-reactivity of anti-human MBL polyclonal antibody with porcine MBL. A full-length porcine liver MBL cDNA was isolated and the predicted amino acid sequence exhibited 64.9% identity with human MBL and 50.2% and 56.7% identity with rat A and C MBL, respectively. Furthermore, Northern blot analysis demonstrated the presence of a single (approximately 1.4-1.6 kilobase pair) transcript in porcine liver. Addition of purified porcine MBL to MBL-deficient human sera augmented N-acetylglucosamine inhibitable C3 deposition to mannan-coated plates in a dose-dependent manner. Taken together, these data demonstrate that porcine and human MBL are highly conserved, sharing structural and functional characteristics. Binding of mannose-binding lectin (MBL), a C-type lectin, and its associated serine proteases, MASP-1 and MASP-2, to cell surface carbohydrates activates the lectin complement pathway. As MBL plays an important MBIL), a C-type lectin, and its associated serine proteases, MASP-1 and MASP-2, to cell surface carbohydrates activates the lectin complement pathway. As MBL plays an important role in innate immunity, it has been cloned and characterized in several species. While the pig may be used as a source of organs/tissues for xenotransplantation, little is known about its MBL, thus, we report the isolation of three monomeric forms of MBL from porcine serum. Sodium dodecyl sulphate-polyacrylamide gel electrophoresis and Coomassie staining of reduced porcine MBL revealed the presence of three monomeric forms with approximate molecular masses of 30 000, 32 000 and 34 000. Protein. . . sequencing identified these monomeric forms as one single protein, suggesting post-translational modification. Complement is a major participant in post-ischemic reperfusion injury. The classical and alternative complement pathways have been extensively studied; however, the role of the lectin complement pathway (LCP) in inflammation has not been investigated since inhibitors of MBL have not been described. In order to delineate the participation of the LCP, we generated antibodies to rat mannose binding lectin (MBL). In this study, antibodies (Ab) were produced and characterized for potential use in further dissecting the role of the LCP in rat models of human disease. Polyclonal and monoclonal antibodies were produced in rabbits and mice using purified MBL isolated from models of human disease. Polyclonal and monoclonal antibodies were produced in rabbits and mice using purified MBL isolated from rat sera by affinity chromatography and standard immunization techniques. All antibodies were screened using 2 different ELISA systems (binding to mannan or BSA coupled to N-acetyl-D-glucosamine; BSA-GlcNAc) to detect complement activation and deposition of C3. Monoclonal Ab P7E4 inhibited C3 deposition onto BSA-GlcNAc coated plates in a concentration-dependent manner with maximal inhibition (apprx80%) occurring at 10 mug/mL. Similarly, Fab fragments of the polyclonal antibody inhibited complement deposition in a concentration dependent manner. Western blot analysis was performed to determine the isoform(s) of rat MBL that the antibodies recognized. While the polyclonal Ab recognized multiple oligomers of A and C isoforms under non-reducing conditions, mAb P7E4 only recognized the A isoform. Similar results were obtained under reducing conditions in that the polyclonal Ab recognized both forms while only the A isoform was recognized by P7E4. These data confirm that the antibodies recognize rat mannose binding lectin, inhibit the function of MBL and may serve as useful reagents in studying the lectin complement pathway in rat models of human disease.

AB Complement is an important mediator of vascular injury following oxidative stress. We recently demonstrated that complement activation following endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the lectin complement pathway. Here, we investigated whether nine plant lectins which have a binding profile similar to that of MBL competitively inhibit MBL deposition and subsequent complement activation following human umbilical vein endothelial cell (HUVEC) oxidative stress. HUVEC oxidative stress (1% 02, 24 h) significantly increased Ulex europaeus agglutinin II (UEA-II) binding by 72.+-.9% compared to normoxic cells. UEA-II inhibited MBL binding to HUVEC in a concn.-dependent manner following oxidative stress. Further, MBL inhibited UEA-II binding to HUVEC in a concn.-dependent manner following oxidative stress, suggesting a common ligand. UEA-II (ltoreq. 100 mu.mol/L) did not attenuate the hemolytic activity, nor did it inhibit C3a des Arg formation from alternative or classical complement pathway-specific hemolytic assays. C3 deposition (measured by ELISA) following HUVEC oxidative stress was inhibited by UEA-II in a concn.-dependent manner (IC50 = 10 pmol/L). UEA-II inhibited C3 and MBL co-localization (confocal microscopy) in a concn.-dependent manner on HUVEC following oxidative stress (IC50 and pmzeq. 1 pmol/L). Finally, UEA-II significantly inhibited complement-dependent neutrophil chemotaxis, but failed to inhibit fMLP-mediated chemotaxis, following endothelial oxidative stress. These data demonstrate that UEA-II is a novel, potent inhibitor of human MBL deposition and complement activation following human endothelial oxidative stress.

                             Complement is an important mediator of vascular injury following oxidative stress. We recently demonstrated that complement activation following endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the
                        endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the lactin complement pathway. Here, we investigated whether nine plant lectins which have a binding profile similar to that of MBL competitively inhibit MBL deposition and subsequent complement activation following human umbilical vein endothelial cell (HUVEC) oxidative stress. HUVEC oxidative stress (1% O2, 24 h) significantly increased Ulex europaeus agglutinin II (UEA-II) binding by 72.+-.9% compared to normoxic cells. UEA-II inhibited MBL binding to 'HUVEC in a concn.-dependent manner following oxidative stress. Further, MBL inhibited UEA-II binding to HUVEC in a concn.-dependent manner following oxidative stress, suggesting a common ligand. UEA-II (.ltoreq. 100 .mu.mol/L) did not attenuate the hemolytic activity, nor did it inhibit C3a des Arg formation from alternative or classical complement pathway-specific hemolytic assays. C3 deposition (measured by ELISA) following HUVEC oxidative stress was inhibited by UEA-II in a concn.-dependent manner (IC50 = 10 pmol/L). UEA-II inhibited C3 and MBL co-localization (confocal microscopy) in a concn.-dependent manner on HUVEC following oxidative stress (IC50 .apprxeq. l pmol/L). Finally, UEA-II significantly inhibited complement-dependent neutrophil chemotaxis, but failed to inhibit fMLP-mediated chemotaxis, following endothelial oxidative stress. These data demonstrate that UEA-II is a novel, potent inhibitor of human MBL deposition and complement activation following human endothelial oxidative stress.

The complement system plays an important role in mediating tissue injury after oxidative stress. The role of mannose-binding after oxidative stress. The role of mannose-binding lectin (MBL) and the lectin complement
pathway (LCP) in mediating complement activation after endothelial oxidative stress was investigated. iC3b deposition on hypoxic (24 hours; 1% O(2))/reoxygenated (3 hours; 21% O(2)) human endothelial cells was attenuated by N-acetyl-D-glucosamine or D-mannose, but not L-mannose, in a dose-dependent manner. Endothelial iC3b deposition after oxidative stress was also attenuated in MBL-deficient serum. L-mannose, in a dose-dependent manner. Endothelial iClb deposition after oxidative stress was also attenuated in MBL-deficient serum.

Novel, functionally inhibitory, anti-human MBL monoclonal antibodies attenuated MBL-dependent C3 deposition on mannan-coated plates in a dose-dependent manner. Treatment of human serum with anti-MBL monoclonal antibodies inhibited MBL and C3 deposition after endothelial oxidative stress. Consistent with our in vitro findings, C3 and MBL immunostaining throughout the ischemic area at risk increased during rat myocardial reperfusion in vivo. These data suggest that the LCP mediates complement activation after tissue oxidative stress. Inhibition of MBL may represent a novel therapeutic strategy for ischemia/reperfusion injury and other complement-mediated disease states.

The lectin complement pathway is initiated
by binding of mannose-binding lectin (
MBL) and MBL-associated serine protease (MASP) to
carbohydrates. In the human lectin pathway, MASP-1 and MASP-2 are involved
in the proteolysis of C4, C2 and C3. Here we report that the human
MBL-MASP complex contains a new 22 kDa protein (small MBL
-associated protein (sMAP)) bound to MASP-1. Analysis of the nucleotide
sequence of sMAP cDNA revealed that it is a truncated form of MASP-2,
consisting of the first two domains (i.e. the first internal repeat and
the epidermal growth factor-like domain) with four different C-terminal
amino acids. sMAP mRNAs are expressed in liver by alternative
polyadenylation of the MASP-2 gene, in which a sMAP-specific exon
containing an 'in-frame stop codon and a polyadenylation signal is used.
The involvement of sMAP in the MBL-MASP complex suggests that
the activation mechanism of the lectin pathway is more complicated than
that of the classical pathway.
A truncated form of mannose-binding lectin
-associated serine protease (MASP)-2 expressed by alternative
polyadenylation is a component of the lectin complement
pathway.
The lectin complement pathway is initiated
                                                                                             199906

PRIORITY APPLN. INFO:

B The invention relates to methods and products for regulating lectin complement pathway assocd. complement activation. The methods include both in vitro and in vivo methods for inhibiting lectin complement pathway assocd. complement activation. The methods are accomplished by contacting a mammalian cell having surface exposed MBL ligand with an effective amt. of a mannan binding lectin (MBL) receptor antagonist to inhibit lectin complement pathway assocd. complement pathway assocd. complement pathway assocd. complement activation. The mannan binding lectin receptor antagonist may be administered to a subject to prevent cellular injury mediated by lectin complement pathway assocd. complement activation. The products of the invention include
                 injury mediated by lectin complement pathway assocd. complement activation. The products of the invention include compns. of a mannan binding lectin receptor antagonist. The mannan binding lectin receptor antagonist is an isolated mannan binding lectin that selectively binds to a human mannan binding lectin epitope and that
 inhibits lectim complement pathway assocd. complement activation.

lectin complement pathway (LCP), which is initiated by deposition of the mannose-binding lectin (MBL), is largely responsible for activating complement on endothelial cells following periods of oxidative stress. Identifying functional inhibitors that block MBL binding will be useful in characterizing the role of the LCP in disease models. The human cytokeratin peptide SFGSGFGGGY has been identified as a molecular mimic of N-acetyl-D-glucosamine (GlcNAc), a known ligand of MBL. Thus, we hypothesized that this peptide would specifically bind to MBL and functionally inhibit the LCP on endothelial cells following oxidative stress. Using a BIAcore 3000 optical biosensor, competition experiments were performed to demonstrate that the peptide SFGSGFGGGY inhibits binding of purified recombinant human MBL to GlcNAc in a concentration-dependent manner. Solution affinity data generated by BIAcore indicate this peptide binds to MBL with an affinity (K(D)) of 5 x 10(-5) mol/L. Pretreatment of human serum (30%) with the GlcNAc-mimicking peptide (10-50 microg/ml) significantly attenuated MBL and C3 deposition on human endothelial cells subjected to oxidative stress in a dose-dependent manner, as demonstrated by cell surface. . . VCAM-l expression following oxidative stress. These data indicate that a short peptide sequence that mimics GlcNAc can specifically bind to MBL and functionally inhibit the proinflammatory action of the LCP on oxidatively stressed endothelial cells.
                                                            endothelial cells.

Reperfusion of ischemic myocardium initiates an inflammatory-like process
leading to additional tissue injury. Following myocardial ischemia and
reperfusion of ischemic myocardium initiates an inflammatory-like process
leading to additional tissue injury. Following myocardial ischemia and
reperfusion (MI/R), complement is activated with a subsequent increase in
pro-inflammatory cytokines and adhesion molecule gene expression.
Increasing evidence suggests that the lectin complement
pathway (LCP) is involved in initiating the complement
cascade following MI/R. In this study, we assessed the result of
inhibiting complement activation via the LCP on the
expression of inflammatory genes (cytokines and adhesion molecules)
following MI/R. Male Sprague-Davley rats were subjected to 30 minutes of
ischemia followed by 4 hours of reperfusion. Prior to occlusion, rats were
treated with 1 mg/kg PT24 (a mAb against rat mannose
binding lectin-MBL A) or GS-1 (an isotype
control antibody). Following 4 hours of reperfusion, the hearts were
removed, washed in saline and the area at risk was frozen in liquid
nitrogen. Total RNA was isolated using the acid-quanidinium thiocyanate
extraction procedure and subjected to DNase treatment. Semi-quanitative
RT-PCR was performed to assess mRNA levels of ICAM-1, TNF-alpha, INOS,
eNOS, SOD (CU/Zn and Mn) GM-CSF and IL-1 alpha, in sham operated animals
and those treated with GS-1 or PT24 as described above.
Ischemia-reperfusion resulted in the increased expression of ICAM-1,
iNOS*, TNF-alpha*, CM-CSF* and IL-alpha* compared to sham operated
expression for ICAM-1, CM-CSF*, IL-1 alpha, in sham operated
expression for ICAM-1, CM-CSF*, IL-1 alpha* and iNOS. These data suggest
that inhibition of MBL A and the lectin
complement pathway results in the attenuation of
inflammatory gene expression and that this gene regulation may be
partially responsible for the protection from MI/R injury, * p < 0.05.

Complement plays a significant role in mediating endothelial damage
following oxidative stress. We have previously demonstrated that the
lactin complement pathway (LCP),
which is initiated by mannose binding lactin
(MBL) deposition, is largely responsible for activating
complement after endothelial oxidative stress. Identifying functional
inhibitors of MBL will be useful in characterizing the
role of the LCP following periods of oxidative stress. To date,
peptide analogues specific for MBL have not been identified. The
human cytokeratin peptide, SFGSGFGGGY, has previously been identified as a
molecular mimic of N-acetyl-D-glucosamine (GlcNAC), a natural ligand of
MBL. Thus, we hypothesized that the sequence SFGSGFGGGY would
                                                                                                                             English
                                numan cytokeratin peptide, SFGSGFGGGY, has previously been identified as a molecular mimic of N-acetyl-D-glucosamine (GlcNAc), a natural ligand of MBL. Thus, we hypothesized that the sequence SFGSGFGGGY would specifically bind MBL and functionally inhibit the LCP. Using a BIAcore 3000 optical biosensor, we performed competition experiments to demonstrate that the peptide SFGSGFGGGY can inhibit binding of recombinant human MBL to GlcNAc in a concentration dependent manner. Solution affinity data generated by BIAcore indicate this peptide binds to MBL with an affinity (KD) of 5 X 10-5 M., Pretreatment. of human serum (308) with the GlcNAc-mimicking peptide (10 - 50 mug/ml) significantly attenuated C3 deposition on oxidatively stressed endothelial cells in a dose dependent manner, as demonstrated by ELISA. Confocal microscopy experiments revealed that complement inhibition coincided with a decrease in MBL deposition. Additionally, this peptide significantly attenuated the complement-dependent expression of vascular cell adhesion molecule (VCAM)-las shown by ELISA. These data indicate that a short peptide sequence that mimics GlcNAc can specifically bind to MBL, with a physiologically relevant affinity, and functionally inhibit the pro-inflammatory action of the LCP on oxidatively stressed endothelial cells. Further, this is the first report to demonstrate that MBL is capable of specifically binding a non-carbohydrate ligand. Complement plays a significant role in mediating endothelial damage following oxidative stress. We have previously demonstrated that the lectin complement pathway (LCP), which is initiated by mannose binding lectin.

role in innate immunity, it has been cloned and characterized in several species. While the pig may be used as a source of organs/tissues for xenotransplantation, little is known about its MBL, thus, we report the isolation of three monomeric forms of MBL from porcine serum. Sodium dodecyl sulphate-polyacrylamide gel electrophoresis and Coomassie staining of reduced porcine MBL revealed the presence of three monomeric forms with approximate molecular masses of 30 000, 32 000 and 34 000. Protein sequencing identified these monomeric forms as one single protein, suggesting post-translational modification. Western blot analysis demonstrated the cross-reactivity of anti-human MBL polyclonal antibody with porcine MBL. A full-length porcine liver MBL cDNA was isolated and the predicted amino acid sequence exhibited 64.98 identity with human MBL and 50.28 and 56.78 identity with rat A and C MBL, respectively. Furthermore, Northern blot analysis demonstrated the presence of a single (approximately 1.4-1.6 kilobase pair) transcript in porcine liver. Addition of purified porcine MBL to MBL-deficient human sera augmented N-acetylglucosamine inhibitable C3 deposition to mannan-coated plates in a dose-dependent manner. Taken together, these data demonstrate that porcine and human MBL are highly conserved, sharing structural and functional characteristics. Binding of mannose-binding lectin (MBL), a C-type lectin, and its associated serine proteases, MASP-1 and MASP-2, to cell surface carbohydrates activates the lectin complement pathway. As MBL plays an important role in innate immunity, it has been cloned and characterized in several species. Complement is a major participant in post-ischemic reperfusion injury. The classical and alternative complement pathways have been extensively studied; however, the role of the lectin complement pathway (LCP) in inflammation has not been investigated since inhibitors of MBL have not been described. In order to delineate the participation of the LCP, we generated antibodies to rat mannose binding lectin (

MBL). In this study, antibodies (Ab) were produced and characterized for potential use in further dissecting the role of the LCP in rat models of human disease. Polyclonal and monoclonal antibodies were produced in rabbits and mice using purified MBL isolated from rat sera by affinity chromatography and standard immunization techniques. All antibodies were screened using 2 different ELISA systems (binding to mannan or BSA coupled to N-acetyl-D-glucosamine; BSA-GlcNAc) to detect complement activation and deposition of C3. Monoclonal Ab P7E4 inhibited C3 deposition onto BSA-GlcNAc coated plates in a concentration-dependent manner with maximal inhibition (apprx80%) occurring at 10 mug/mL. Similarly, Fab fragments of the polyclonal antibody inhibited complement deposition in a concentration dependent manner. Western blot analysis was performed to determine the isoform(s) of rat MBL that the antibodies recognized while the polyclonal Ab recognized multiple oligomers of A and C isoforms under non-reducing conditions, mAb P7E4 only recognized the A isoform. Similar results were obtained under reducing conditions in that the polyclonal Ab recognized both forms while only the A isoform was recognized by P7E4. These data confirm that the antibodies recognizer rat mannose binding lectin, inhibit the function of MBL and may serve as useful English SUMMARY LANGUAGE: English A isoform was recognized by F/64. Complement is an important mediator of vascular injury following oxidative stress. We recently demonstrated that complement activation following endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the lectin complement pathway. Here, we investigated whether nine plant lectins which have a binding profile similar to that of MBL competitively inhibit

MBL deposition and subsequent complement activation following human umbilical vein endothelial cell (MUVEC) oxidative stress. HUVEC oxidative stress (18 O2, 24 h) significantly increased Ulex europaeus agglutinin II (UEA-II) binding by 72.+-.9% compared to normoxic cells. UEA-II inhibited MBL binding to HUVEC in a concn.-dependent manner following oxidative stress. Further, MBL inhibited UEA-II binding to HUVEC in a concn.-dependent manner following oxidative stress, suggesting a common ligand. UEA-II (.ltoreq. 100 .mu.mol/L) did not attenuate the hemolytic activity, nor did it inhibit C3a des Arg formation from alternative or classical complement pathway-specific hemolytic assays. C3 deposition (measured by ELISA) following HUVEC oxidative stress was inhibited by UEA-II in a concn.-dependent manner (IC50 = 10 pmol/L). UEA-II inhibited C3 and MBL co-localization (confocal microscopy) in a concn.-dependent manner on HUVEC following oxidative stress (IC50 .apprxeq. 1 pmol/L). Finally, UEA-II significantly inhibited complement-dependent neutrophil chemotaxis, but failed to inhibit fMLP-mediated chemotaxis, following endothelial oxidative stress. These data demonstrate that UEA-II is a novel, potent inhibitor of human MBL deposition and complement activation following human endothelial oxidative stress.

                                Complement is an important mediator of vascular injury following oxidative stress. We recently demonstrated that complement activation following endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the
                            endothelial oxidative stress is mediated by mannose-binding lectin (MBL) and activation of the lectin complement pathway. Here, we investigated whether nine plant lectins which have a binding profile similar to that of MBL competitively inhibit MBL deposition and subsequent complement activation following human umbilical vein endothelial cell (HUVEC) oxidative stress. HUVEC oxidative stress (1% 02, 24 h) significantly increased Ulex europaeus agglutinin II (UEA-II) binding by 72.+-.9% compared to normoxic cells. UEA-II inhibited MBL binding to HUVEC in a concn.-dependent manner following oxidative stress. Further, MBL inhibited UEA-II binding to HUVEC in a concn.-dependent manner following oxidative stress, suggesting a common ligand. UEA-II (.ltoreq. 100 .mu.mol/L) did not attenuate the hemolytic activity, nor did it inhibit C3a des Arg formation from alternative or classical complement pathway-specific hemolytic assays. C3 deposition (measured by ELISA) following HUVEC oxidative stress was inhibited by UEA-II in a concn.-dependent manner (IC50 = 10 pmol/L). UEA-II inhibited C3 and MBL co-localization (confocal microscopy) in a concn.-dependent manner on HUVEC following oxidative stress (IC50 .apprxeq. 1 pmol/L). Finally, UEA-II significantly inhibited complement-dependent neutrophil chemotaxis, but failed to inhibit MLP-mediated chemotaxis, following endothelial oxidative stress. These data demonstrate that UEA-II is a novel, potent inhibitor of human MBL deposition and complement activation following human endothelial oxidative stress.

            after oxidative stress. The role of mannose-binding lectin (MBL) and the lectin complement activation after endothelial oxidative stress was investigated. iC3b deposition on hypoxic (24 hours; 1% O(2))/reoxygenated (3 hours;. . N-acetyl-D-glucosamine or D-mannose, but not L-mannose, in a dose-dependent manner. Endothelial iC3b deposition after oxidative stress was also attenuated in MBL deficient serum. Novel, functionally inhibitory, anti-human MBL monoclonal antibodies attenuated MBL-dependent C3 deposition on mannan-coated plates in a dose-dependent manner. Treatment of human serum with anti-MBL monoclonal antibodies inhibited MBL and C3 deposition after endothelial oxidative stress. Consistent with our in vitro findings, C3 and MBL immunostaining throughout the ischemic area at risk increased during rat myocardial reperfusion in vivo. These data suggest that the LCP mediates complement activation after tissue oxidative stress. Inhibition of MBL may represent a novel therapeutic strategy for ischemia/reperfusion injury and other complement-mediated disease states.

Complement plays a significant role in mediating endothelial injury following oxidative stress. We have previously demonstrated that the lectin complement pathway (LCP), which is initiated by deposition of the mannose-binding lectin (MBL), is largely responsible for activating complement on endothelial cells following periods of oxidative stress. Identifying functional inhibitors that block MBL binding will be useful in characterizing the role of the LCP in disease models. The human cytokeratin peptide SFGSGFGGGY has been identified as a molecular mimic of N-acetyl-D-glucosamine (GlcNAc), a known ligand of MBL. Thus, we hypothesized that this peptide would specifically bind to MBL and functionally inhibit the LCP on endothelial cells following oxidative stress. Using a BIAcore 3000 optical biosensor, competition experiments were performed to demonstrate that the peptide SFGSGFGGY inhibits binding of purified recombinant human MBL to GlcNAc in a concentration-dependent manner. Solution affinity data generated by BIAcore indicate this peptide binds to MBL with an affinity (K(D)) of 5 x 10(-5) mol/L. Pretreatment of human serum (30%) with the GlcNAc-mimicking peptide (10-50 microg/ml) significantly attenuated MBL and C3 deposition on human endothelial cells subjected to oxidative stress in a dose-dependent manner, as demonstrated by cell surface ELISA and confocal microscopy. Additionally, this decapeptide sequence attenuated complement-dependent VCAM-1 expression following oxidative stress. These data indicate that a short peptide sequence that mimics GlcNAc can specifically bind to MBL and functionally inhibit the proinflammatory action of the LCP on oxidatively stressed endothelial cells.
